Learning to Love the Lambda in the Stream

Introduction to Java 8 Lambda and Functional Interfaces

Speaker Introduction

- Richard Roda
- Sr. Technical Lead at DXC Technology
- Over 15 years of Java development experience
- OCA Java and Security+ certifications
- Linked In: https://www.linkedin.com/in/richardroda
- Twitter: @Richard_Roda
- These slides (pdf): https://tinyurl.com/love-lambda

What is a Lambda Expression?

- In Java, it is an unnamed function that may be bound to an interface as an object.
- Similar to a closure, class members, *effectively final* arguments and local variables are available to it.
- Lambdas may only exist when assigned to a Functional Interface, including being passed in as a parameter.
- An *effectively final* local variable or argument is either declared final, or is not changed such that if the final declaration were added, the code remains valid.

Lambda Examples

- Example 1a

```
Predicate<Integer> isFive = n -> n == 5;
System.out.println(isFive.test(4)); // false
```

- Example 1b

```
Predicate<Integer> mkTestFunc(int value)
    { return n -> n == value; }
Predicate<Integer> isFour = mkTestFunc(4);
System.out.println(isFour.test(4)); // true
```

- Lamdba expressions must be assigned to a functional interface
- `(n -> 5).test(); // Does not compile`

Method References

- Shorthand for a Lambda that only calls a method
- Reference may be on a specific instance, a static method, an instance method on the class, and a constructor.
- For the case of an instance method on a class, the first argument is the instance to apply the method on. Each remaining lambda argument is passed to the remaining method arguments.

```
Stream.of("ab","cd","ef")
.map(String::toUpperCase) // i->i.toUpperCase()- Class
.forEach(System.out::print)//i->System.out.print(i)- Instance
//ABCDEF
```

- For all other cases, each argument is passed into the method in order.

Functional Interface (FI) in Java 8

- "A functional interface is any interface that contains only one abstract method." – [Oracle Java Tutorial]
- The sole abstract method referred to as the *functional method*
- Example 2- Valid Functional Interface

```
@FunctionalInterface // Optional
public interface Example2 {
    int myMethod(); // Functional Method
    boolean equals(Object other); // In Object
    int hashCode(); // In Object
    default int myMethod2() {return myMethod();}
    static int myMethod3() {return 0;}
}
```

Binding Lambda to Example2 FI vs Anonymous Inner class

- Both of these implement myMethod defined in Example2.
- Since there is exactly one abstract functional method, method types and return values are inferred from the FI.

```
public class Example3 {
    static public void main(String[] args) {
        Example2 lambda = () -> 3; // 8 chars
        Example2 innerClass = new Example2() {
            @Override public int myMethod() {
                return 3;
            }
        }; // 5 lines of code, 65 chars
        System.out.println(lambda.myMethod()); // 3
        System.out.println(innerClass.myMethod()); // 3
    }
}
```

Key Functional Interfaces

Functional Interface Conventions

- The abstract method is called the *functional method*
- The following conventions apply for type variables used by Java 8 FIs:
- T - First argument
- U – Second argument
- R – Return Value
- Any of the above are omitted if not used.
- If an FI lacks an argument, T is sometimes used for the return value instead of R.
- May FIs that take one argument have a corresponding two argument version prefixed with “Bi”.

Predicate<T>

- Accepts an argument, returns a `boolean`.
- Commonly used to select matching elements, or filter for matching elements.
- Functional method: `boolean test(T t)`
- 2 argument FI: `BiPredicate<T,U>`
- Related Primitive FIs: `DoublePredicate`, `IntPredicate`, `LongPredicate`

Consumer<T>

- Accepts an argument. Returns no value (void).
- Commonly used to perform an operation, such as printing.
- Collections and Streams have this method to apply an action to each of their elements:

```
void forEach(Consumer<? super T> action)
```

- Useful for implementing a Visitor pattern via `forEach`
- Functional Method: `void accept(T t)`
- 2 Argument FI: `BiConsumer<T,U>`
- Related Primitive FIs: `DoubleConsumer`, `IntConsumer`, and `LongConsumer`

Supplier<R>

- Accepts no arguments, returns a result
- Commonly used to provide an origin value to an algorithm.
- Useful for implementing the Factory pattern.
- Functional Method: `R get()`
- Related Primitive FIs: `DoubleSupplier`, `IntSupplier`, `LongSupplier`

Function<T,R>

- Accepts an argument, returns a result.
- Commonly used to compute a result, or to map one value to another value.
- Functional Method: `R apply(T t)`
- 2 Argument FI: `BiFunction<T,U,R>`
- Related Primitive FIs: `[Double,Int,Long]Function`, `[Double,Int,Long]To [Double,Int,Long]Function`, `To [Double,Int,Long]Function`, `To[Double,Int,Long]BiFunction`

UnaryOperator<T>

- Accepts an argument, returns the same type of result as its argument.
- Used to compute a result or map a value to the same type as the input.
- Functional Method: `T apply(T t)`
- 2 Argument FI: `BinaryOperator<T>`
- Related Primitive FIs: `[Double,Int,Long]UnaryOperator`, `[Double,Int,Long]BinaryOperator`
- `UnaryOperator<T>` extends `Function<T,T>`
- `BinaryOperator<T>` extends `BiFunction<T,T,T>`

Comparator<T>

- Accepts two arguments, and returns an integer.
- Used to compare objects, and to impose a *total ordering* on a collection of objects.
- Functional Interface: `int compare(T o1, T o2)`
  - When o1 < o2, returns <= -1
  - When o1 = o2, returns 0
  - When o1 > o2, returns >= 1
- Even though Comparator has been around since the early days, it is a functional interface because it has a single abstract method.

Streams

Not to be confused with IO Streams

Java Stream Definition

- Abstraction for computation of elements.
- A computation structure, not a data structure.
- A stream consists of
  1. A data source, such as a collection, file, or computation. May be infinite, such as the set of numbers starting at 0. A data source is *lazy*.
  2. Zero or more intermediate operations.
     - Accepts a stream and returns a another stream with the operation appended to it.
     - *Lazy*: Only executed when a terminal operation processed the stream.
  3. A terminal operation
     - Returns a result, such as a number or a collection.
     - *Eager:* It requests the elements from the final stream, which has the effect of pulling elements from the data source and applying the intermediate operations to them. A stream is a passive description of a computation until a terminal operation is applied.
     - Closes the stream. Any further operations are invalid and result in an IllegalStateException.

Add a collection of numbers

- Given `Collection<Integer> numbers` that has integers from 1 to 1000, add the collection.
- For Loop

```
int total = 0;
for(Integer number : numbers) {total += number;}
return total; // 500500
```

- Stream reduction

```
return numbers.stream().reduce(0, (i,sum) -> i+sum); // 500500
```

- Same Sum using an IntStream

```
return IntStream.rangeClosed(1, 1000).sum(); // 500500
```

Breaking Down the Stream

```
stream(Collection<Integer> numbers) {
    return numbers.stream() // Data Source
        .reduce(0, (i,sum) -> i+sum); // Terminal Operation
}
```

- All streams have a data source, zero or more intermediate operations, and a terminal operation.
- `numbers` collection is the data source.
- `reduce` is a terminal *reduction* on the stream.
- A reduction distills all of the values in a given stream to a single value.
- Integer reduction examples: sum, average, median, min, and max.
- The first argument to `reduce` is the identity argument. For addition, it is 0. For a multiplication it is 1.
- The lambda is a `BinaryOperator<Integer>` that is given a running total and the current element. They are processed by adding them together.

Primitive Streams

- `IntStream`, `LongStream`, and `DoubleStream`
- Offers a performance benefit over generic stream by avoiding boxing of primitive computations.
- Offers additional methods, such as `sum()`, `min()`, `max()`, `average()`, and `summaryStatistics()`.
- Can replace a traditional for loop

```
IntStream.range(0, 10).forEach(System.out::println); // Print 0-9
```

- Use `mapToInt`, `mapToLong`, `mapToDouble`, and `mapToObj` to convert an existing stream to an `IntStream`, `LongStream`, `DoubleStream`, and `Stream<T>` respectively.
- Use the `boxed()` method to convert a primitive stream to its equivalent object stream by boxing the primitive values as follows:
  - `IntStream` to `Stream<Integer>`
  - `LongStream` to `Stream<Long>`
  - `DoubleStream` to `Stream<Double>`

Map

- Apply a computation on stream elements.
- May be used to change the element type of a stream by returning values of a different type.

```
Stream<Character> s = IntStream.range(65, 75)
   .mapToObj(i->(char)i); // Stream<Character>
s.forEach(System.out::print); // ABCDEFGHIJ
```

- Change values, but keep data type (int).

```
IntStream.range(0, 10).map(i -> i*10)
.forEach(System.out::println); // 0, 10 ... 90
```

Filter

The `filter` intermediate operation creates a new stream with the contents of the previous stream where the `Predicate<T>` or primitive predicate is `true`.

```
IntSummaryStatistics summaryStatistics =
IntStream.range(0, 1000) // Data Source
.filter(i -> i %4 == 0) // Intermediate Operation
.summaryStatistics(); // Terminal Operation
System.out.println(summaryStatistics);
//count=250, sum=124500, min=0, average=498.000000, max=996
```

Collecting – The Stream.Collect Method

- The `Stream.collect` method performs a *mutable reduction*.
- This is a terminal operation that creates a new object that has each element of the stream applied to it. Example: convert a Stream to a Collection.
- ```
  List<Integer> ints = IntStream.of(1,2,2,3,4,5).boxed()
  .collect(Collectors.toList()); System.out.println(ints);
  // [1, 2, 2, 3, 4, 5]
  ```
- ```
  Set<Integer> intSet = IntStream.of(1,2,2,3,4,5).boxed()
  .collect(Collectors.toSet()); System.out.println(intSet);
  // [1, 2, 3, 4, 5]
  ```
- ```
  // Custom collection type with a sort applied to it.
  LinkedHashSet<Integer> sortedSet = IntStream.of(1,2,2,3,4,5)
  .boxed().sorted(Comparator.reverseOrder())
  .collect(Collectors.toCollection(LinkedHashSet::new));
  System.out.println(sortedSet);
  // [5, 4, 3, 2, 1]
  ```
  ```

Partition

- The Partition collector uses a `Predicate<T>` to create a map with the keys **`false`** and **`true`**.
- Both the **`false`** and **`true`** key and value always exist in the map even if the corresponding value is not present. In such a case, the value will be an empty collection, an empty optional, or a sum or count of 0.
- Use the predicate in the previous example to create a map with elements divisible by 4 and not divisible by 4.

```
Map<Boolean,Integer> summap =
IntStream.range(0, 1000).boxed()
.collect(partitioningBy(i -> i%4==0, summingInt(i -> i)));
System.out.println(summap); // {false=375000, true=124500}
```

The `summingInt` collector is an example of a *downstream collector*. In this case, it accepts the result of the partitioning by collector and produces a sum reduction of the values.

Grouping By

- For the next example, consider the following stream producing function
- `static Stream<String> aboutJack() {`

```
return Stream.of("All","work","and","no","play","makes",
"jack","a","dull","boy","but","all","play","and","no",
"work" ,"makes","jack","a","fool"); }
```

- Group each word by starting letter, in alphabetical order

```
aboutJack().sorted().collect(
    Collectors.groupingBy(s -> s.charAt(0),
    TreeMap::new,Collectors.toCollection(TreeSet::new)));
/* A=[All], a=[a, all, and], b=[boy, but], d=[dull],
f=[fool], j=[jack], m=[makes], n=[no], p=[play], w=[work] */
```

Grouping By Concurrent

- Streams may be processed in parallel by using the `parallel` method using concurrent collectors and data structures.

```
aboutJack().parallel().collect( Collectors.groupingByConcurrent(
s -> s.charAt(0), ConcurrentSkipListMap::new,
Collectors.toCollection(ConcurrentSkipListSet::new)));
/* A=[All], a=[a, all, and], b=[boy, but], d=[dull], f=[fool],
j=[jack], m=[makes], n=[no], p=[play], w=[work] */
```

- Count the words
- `aboutJack().parallel().collect(Collectors.groupingByConcurrent(`

```
s -> s, ConcurrentSkipListMap::new, Collectors.counting()));
/* All=1, a=2, all=1, and=2, boy=1, but=1, dull=1, fool=1, jack=2,
makes=2, no=2, play=2, work=2 */
```

Joining

- A process where a stream of `CharSequence` is concatenated together to form a string. Recall the `aboutJack` stream:

```
static Stream<String> aboutJack() { return Stream.of(
"All","work","and","no","play","makes","jack","a","dull",
"boy","but","all","play","and","no","work","makes",
"jack","a","fool"); }
```

- Join this into words separated with a space:

```
aboutJack().collect(Collectors.joining(" "));
/* All work and no play makes jack a dull boy but all play
and no work makes jack a fool */
```

Unit Testing a Stream

Unit Tests as Builders for a Stream

Unit Test Using Builder

Passes through the builder or adds an intermediate operation for testing.

Unit Test Using Decorator

Decorate the lambdas used in the stream with testing functionality
